

Authentication and Authorization

Ensure appropriate access for appropriate people

- 8 Demo

Authentication vs Authorization

Authentication (AuthN)

- Verifies **who you are**
- Like showing your ID at airport
- Common methods:
 - Username/password
 - Biometrics
 - Security tokens

Authorization (AuthZ)

- Determines **what you can do**
- Like hotel key card access
- Implementation through:
 - Roles (RBAC)
 - Permissions
 - Access Control Lists

Authentication Methods

Common Authentication Methods

- **Knowledge-based:**
 - Passwords
 - Security questions
 - PIN numbers
- **Possession-based:**
 - Security tokens
 - Mobile devices
 - Smart cards
- **Inference-based:**
 - Fingerprints
 - Face recognition
 - Voice recognition

Authorization Types

Role-Based Access Control (RBAC):

- Permissions assigned to roles
- Users assigned to roles
- Example: Admin, Editor, Viewer

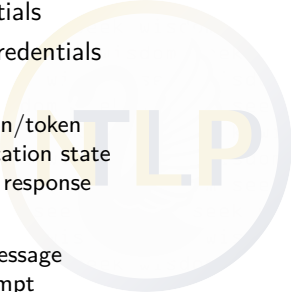

Attribute-Based Access Control (ABAC):

- Based on user attributes
- Context-aware decisions
- Example: Location, time, device

Resource-Based Access Control:

- Permissions tied to resources
- Object-level security
- Example: Document ownership

Authentication Flow Example

- 
- 1 User enters credentials
 - 2 System validates credentials
 - 3 If valid:
 - Generate session/token
 - Store authentication state
 - Return success response
 - 4 If invalid:
 - Return error message
 - Log failed attempt
 - Implement security measures

Best Practices

Security Guidelines

- Use strong password policies
- Implement MFA where possible
- Secure credential storage
- Regular security audits
- Session management
- Rate limiting

Common Mistakes

- Plain text password storage
- Weak password requirements
- Missing access controls
- Insufficient logging

The Authentication Challenge

Modern Web Architecture:

- Frontend and Backend are separate applications
- They communicate through HTTP/WebSocket APIs
- Often running on different domains

The Problem:

- 1 User logs in with username/password
- 2 But... we can't ask for password on every request!
- 3 We need a way to **remember** authenticated users
- 4 And verify their identity for each request

Traditional Solutions and Their Limitations

Session-Based Authentication:

- Server stores session information
- Gives client a session ID
- **Problems:**
 - Needs server storage
 - Doesn't scale well
 - Hard for multiple backends

We Need Something Better:

- No server storage required
- Can verify user without database
- Works across multiple services
- Secure and tamper-proof

Enter JWT: The Solution

JWT as Digital ID Card

How it Works:

- 1 User logs in once with credentials
- 2 Server creates a special digital ID (JWT)
- 3 Server signs it with a secret key
- 4 User presents this ID for future requests
- 5 Server can verify it's genuine using the signature

Just Like a Physical ID Card:

- Contains user information
- Has security features (signature)
- Can be verified without calling issuer
- Has expiration date

JWT Workflow

Frontend (Client)

Backend (Server)

Initial Authentication

Login Request (username + password) → Generate & Sign JWT

Store JWT ← Return JWT Token

API Requests

Request + JWT Bearer Token → Verify JWT Signature

Access Protected Resource ← Return Protected Data

Figure: The workflow for JWT request

What is JWT?

JSON Web Token

- An open standard (**RFC 7519**)
- Self-contained way to securely transmit information
- Information is digitally signed
- Can be verified and trusted
- Compact format: Header.Payload.Signature

Common Use Cases

- Authentication
- Information Exchange
- Authorization
- API Security

JWT Structure

JWT Header

Header Contains:

```
1 {  
2   "alg": "HS256", // Algorithm used  
3   "typ": "JWT"    // Token type  
4 }  
5
```

Common Algorithms (alg):

- **HS256:** HMAC with SHA-256
- **RS256:** RSA with SHA-256
- **ES256:** ECDSA with SHA-256

JWT Payload

Contains Claims:

```
1 {  
2   // Registered claims  
3   "iss": "auth0.com",    // Issuer  
4   "sub": "123456",      // Subject  
5   "exp": 1516239022,    // Expiration Time  
6   "iat": 1516235422,    // Issued At  
7  
8   // Custom claims  
9   "name": "John Doe",  
10  "role": "admin",  
11  "permissions": ["read", "write"]  
12 }  
13
```

JWT Signature

Signature Creation:

```
1 HMACSHA256(  
2   base64UrlEncode(header) + "." +  
3   base64UrlEncode(payload),  
4   secret)  
5
```

Purpose

- Verifies sender identity
- Ensures message wasn't changed
- Prevents token forgery
- Maintains data integrity

JWT Best Practices

Security Guidelines

- Keep tokens secure (use HTTPS)
- Set appropriate expiration times
- Use strong secret keys
- Don't store sensitive data in payload
- Implement token refresh mechanism

Common Mistakes

- Using weak secret keys
- Storing tokens insecurely
- Not validating claims
- Putting sensitive data in payload

JWT vs Session Tokens

JWT

- Stateless
- Self-contained
- Larger size
- Can't be invalidated
- Good for microservices

Session Tokens

- Stateful
- Server-side storage
- Smaller size
- Can be invalidated
- Better for monoliths

Practice in Django

Traditional Django Authentication

Built-in Authentication

- Based on `django.contrib.auth`
- Session-based authentication
- Uses database backend
- Integrated with Django templates

```
1 INSTALLED_APPS = [  
2     'django.contrib.auth',  
3     'django.contrib.sessions',  
4 ]  
5  
6 MIDDLEWARE = [  
7     'django.contrib.sessions.middleware.SessionMiddleware',  
8     'django.contrib.auth.middleware.AuthenticationMiddleware',  
9 ]  
10
```

Session Authentication Flow

- 1 User submits login form
- 2 Django validates credentials
- 3 Creates session in database
- 4 Sets session ID in cookie
- 5 Subsequent requests include cookie

```
1 from django.contrib.auth import login, authenticate
2
3 def login_view(request):
4     user = authenticate(
5         username=username,
6         password=password
7     )
8     if user:
9         login(request, user) # Creates session
10
```

Modern Django REST Authentication

Challenges with Traditional Approach:

- Frontend/Backend separation
- Mobile app support
- Cross-origin requests
- Stateless architecture

Solution:

- Django REST Framework
- JWT Authentication
- Token-based approach

Setting Up JWT in Django

```
1 # settings.py
2 INSTALLED_APPS = [
3     'rest_framework',
4     'rest_framework_simplejwt',
5 ]
6
7 REST_FRAMEWORK = {
8     'DEFAULT_AUTHENTICATION_CLASSES': [
9         'rest_framework_simplejwt.authentication.JWTAuthentication',
10    ],
11 }
12
13 # JWT settings
14 SIMPLE_JWT = {
15     'ACCESS_TOKEN_LIFETIME': timedelta(minutes=60),
16     'REFRESH_TOKEN_LIFETIME': timedelta(days=1),
17     'ROTATE_REFRESH_TOKENS': False,
18 }
19
```

JWT Views and URLs

```
1 # urls.py
2 from rest_framework_simplejwt.views import (
3     TokenObtainPairView,
4     TokenRefreshView,
5 )
6
7 urlpatterns = [
8     path('api/token/',
9         TokenObtainPairView.as_view()),
10    path('api/token/refresh/',
11        TokenRefreshView.as_view()),
12 ]
13
```

Authentication Flow:

- 1 POST credentials to /api/token/
- 2 Receive access & refresh tokens
- 3 Include token in requests

Protecting Views with JWT

```
1 from rest_framework.decorators import api_view, permission_classes
2 from rest_framework.permissions import IsAuthenticated
3 @api_view(['GET'])
4 @permission_classes([IsAuthenticated])
5 def protected_view(request):
6     return Response({'message': 'Protected data', 'user': request.user.
7                       username})
```

Key Points

- DRF handles token validation
- User automatically added to request
- Permissions checked before view execution

Custom Token Claims

```
1 from rest_framework_simplejwt.serializers import (  
2     TokenObtainPairSerializer  
3 )  
4  
5 class CustomTokenSerializer(TokenObtainPairSerializer):  
6     @classmethod  
7     def get_token(cls, user):  
8         token = super().get_token(user)  
9  
10        # Add custom claims  
11        token['username'] = user.username  
12        token['email'] = user.email  
13        token['role'] = user.role  
14  
15        return token  
16
```

- Extend token payload
- Add user-specific data
- Available in frontend

CORS Configuration

```
1 INSTALLED_APPS = [  
2     'corsheaders',  
3 ]  
4  
5 MIDDLEWARE = [  
6     'corsheaders.middleware.CorsMiddleware',  
7     'django.middleware.common.CommonMiddleware',  
8 ]  
9  
10 CORS_ALLOWED_ORIGINS = [  
11     "http://localhost:3000",  
12     "https://frontend.example.com",  
13 ]  
14  
15 CORS_ALLOW_CREDENTIALS = True  
16
```

Testing JWT Authentication

```
1 from rest_framework.test import APITestCase
2 from rest_framework_simplejwt.tokens import RefreshToken
3
4 class AuthTests(APITestCase):
5     def setUp(self):
6         self.user = User.objects.create_user(
7             username='test',
8             password='test123'
9         )
10        self.token = RefreshToken.for_user(self.user)
11        self.client.credentials(
12            HTTP_AUTHORIZATION=f'Bearer {self.token.access_token}'
13        )
14
15    def test_protected_view(self):
16        response = self.client.get('/api/protected/')
17        self.assertEqual(response.status_code, 200)
18
```

Hasura AuthN/AuthZ

Multi-Service Architecture

Figure: Multi-Service JWT Flow

Hasura Authentication Overview

Hasura JWT Requirements

- Hasura expects specific JWT claim format
- Uses x-hasura-* custom claims
- Role-based access control (RBAC)
- Row-level security (RLS)

```
1 {  
2   "sub": "1234567890",  
3   "https://hasura.io/jwt/claims": {  
4     "x-hasura-allowed-roles": ["user", "admin"],  
5     "x-hasura-default-role": "user",  
6     "x-hasura-user-id": "1234567890"  
7   }  
8 }  
9
```

Django Custom Claims for Hasura

```
1 from rest_framework_simplejwt.serializers import (
2     TokenObtainPairSerializer
3 )
4
5 class HasuraTokenSerializer(TokenObtainPairSerializer):
6     @classmethod
7     def get_token(cls, user):
8         token = super().get_token(user)
9
10        # Add Hasura-specific claims
11        hasura_claims = {
12            "https://hasura.io/jwt/claims": {
13                "x-hasura-allowed-roles": [
14                    user.role,
15                    "user"
16                ],
17                "x-hasura-default-role": "user",
18                "x-hasura-user-id": str(user.id),
19                "x-hasura-org-id": str(user.organization_id)
20            }
21        }
22        token.update(hasura_claims)
23        return token
```

Hasura Configuration

```
1 # environment variable
2 HASURA_GRAPHQL_ADMIN_SECRET: "${ADMIN_SECRET}"
3 HASURA_GRAPHQL_UNAUTHORIZED_ROLE: "anonymous"
4
```

Important Settings

- JWT secret must match Django's
- Configure allowed roles
- Set unauthorized role

Hasura Permissions

Role-Based Access Control:

```
1 # Example permission rule
2 {"filter": {
3   "_or": [
4     {"org_id": {"_eq": "X-Hasura-Org-Id"}},
5     {"created_by": {"_eq": "X-Hasura-User-Id"}}]}
6
```

Permission Types

- Row-level select permissions
- Column-level restrictions
- Operation-based (insert/update/delete)
- Dynamic variables from JWT claims

Row and Column Level secure

core_org Try GraphQL Create REST Endpoints New

Permissions

Permissions (Learn more about table permissions)

Full access No access Partial access

Role	insert	select
admin	✓	✓
org_admin	✓	✓
org_owner	✗	✓
org_viewer	✗	✗

Enter new role

Role: org_admin Action: insert

Comments

☐ Add a comment explaining the permissions

Input Validations disabled

Row insert permissions with custom check

Allow role org_admin to insert rows

☐ without any checks (same as select, pre update, delete)

☒ with custom checks

```
{
  "core_project": {
    "organization_id": {
      "eq": "X-Hasura-Org-Id"
    }
  }
}
```

The single row mutation insert_one shares the returning type with the query field. Hence if no select permissions are defined, the insert_one field will also be omitted from the GraphQL schema.

Column insert permissions all columns

Column grants no grants

Backend only disabled

Save Permissions Delete Permissions

Figure: Hasura Permission Control Setting

Testing Hasura Integration

```
1 class HasuraIntegrationTests(APITestCase):
2     def test_jwt_claims_format(self):
3         user = User.objects.create_user(
4             username='test',
5             password='test123',
6             role='admin'
7         )
8         token = HasuraTokenSerializer.get_token(user)
9         claims = token.payload
10
11         self.assertIn('https://hasura.io/jwt/claims', claims)
12         self.assertEqual(
13             claims['https://hasura.io/jwt/claims']
14             ['x-hasura-default-role'],
15             'user'
16         )
17
```

Frontend Authentication Overview

Core Concepts

- JWT stored in cookies/localStorage
- Route protection based on JWT payload
- Role-based access control (RBAC)
- Dynamic UI based on permissions

Key Implementation Points:

- 1 Call api to get the JWT token
- 2 Store and manage JWT
- 3 Decode JWT payload
- 4 Check permissions
- 5 Protect components

JWT in Frontend

```
1 // types/auth.ts
2 interface JWTPayload {
3   user_id: string;
4   roles: string[];
5   permissions: string[];
6   exp: number;
7 }
8
9 // utils/jwt.ts
10 import jwt_decode from 'jwt-decode';
11 export function getPayload(): JWTPayload | null {
12   const token = localStorage.getItem('token');
13   if (!token) return null;
14
15   try {
16     return jwt_decode(token);
17   } catch {
18     return null;
19   }
20 }
21
```

JWT in Frontend

```
1 export function hasPermission(permission: string): boolean {  
2   const payload = getPayload();  
3   return payload?.permissions.includes(permission) ?? false;  
4 }  
5
```

Permission-Based UI Components

```
1 // components/ProtectedComponent.tsx
2 interface Props {
3   requiredPermission: string;
4   children: React.ReactNode;
5   fallback?: React.ReactNode;
6 }
7 export function ProtectedComponent({
8   requiredPermission,
9   children,
10  fallback = null
11 }: Props) {
12   const hasAccess = hasPermission(requiredPermission);
13
14   if (!hasAccess) return fallback;
15
16   return children;
17 }
18
```

Permission-Based UI Components

```
1 // continue from last one
2 // Usage example
3 <ProtectedComponent
4   requiredPermission="posts.create"
5   fallback={<p>No access</p>}
6 >
7   <CreatePostButton />
8 </ProtectedComponent>
9
```

Role-Based Layout

```
1 // layouts/DashboardLayout.tsx
2 export default function DashboardLayout({
3   children
4 }): {
5   children: React.ReactNode
6 }) {
7   const payload = getPayload();
8   const role = payload?.roles[0];
9 }
```

Role-Based Layout

```
1  return (  
2    <div className="layout">  
3      <Sidebar>  
4        {role === 'admin' && (  
5          <>  
6            <NavItem href="/admin/users">Users</NavItem>  
7            <NavItem href="/admin/settings">Settings</NavItem>  
8          </>  
9        )}  
10     {role === 'editor' && (  
11       <>  
12         <NavItem href="/posts">Posts</NavItem>  
13         <NavItem href="/media">Media</NavItem>  
14       </>  
15     )}  
16     </Sidebar>  
17     <main>{children}</main>  
18   </div>  
19 );  
20 }  
21
```

Complete Flow

1 Login & Store Token

- Receive JWT from backend
- Store in secure location
- Decode payload for use

2 Route Protection

- Check token existence
- Verify permissions
- Redirect if needed

3 UI Rendering

- Show/hide based on permissions
- Dynamic navigation
- Protected components

Python Package

Secure API Access with Django REST Framework

- Token-based authentication flow:
 - 1 User requests token with credentials
 - 2 Server validates and returns token
 - 3 Client includes token in API requests

Server Setup: Django REST Framework

```
1 # settings.py
2 INSTALLED_APPS = [
3     'rest_framework',
4     'rest_framework.authtoken',
5 ]
6
7 REST_FRAMEWORK = {
8     'DEFAULT_AUTHENTICATION_CLASSES': [
9         'rest_framework.authentication.TokenAuthentication',
10     ]
11 }
12
13 # views.py
14 from rest_framework.authtoken.views import obtain_auth_token
15 from rest_framework.permissions import IsAuthenticated
16
17
```

Client Usage: Python Package

```
1 import requests
2 # Use token
3 def api_request(token):
4     headers = {'Authorization': f'Token {token}'}
5     response = requests.get(
6         'https://api.example.com/api/data',
7         headers=headers
8     )
9     return response.json()
10
11 # Usage example
12 token = xxxx
13 data = api_request(token)
14
```

Expanded discussion

Authentication & Authorization: Now and future

Authentication Flow Evolution

- Session-based → Token-based
- Traditional → JWT → OAuth
- Single-factor → Multi-factor

Modern Implementation

- Django REST + JWT
- Hasura custom claims
- Microservices architecture

Security Best Practices

- Proper JWT configuration
- HTTPS everywhere
- Secure token storage
- Regular security audits

Key Considerations

- Scalability needs
- Security requirements
- User experience
- Compliance standards

Remember

Authentication (who you are) + Authorization (what you can do)
= Secure Application?

Homework: Setup JWT for both Hasura and Django

- 1 Implement the Django JWT Setup with Endpoints
- 2 Setup Hasura to make sure it has the same JWT Secret Key
- 3 Login and Protected view in frontend

Q&A
